# Variance-based sensitivity analysis for functional inputs

## Methodology

We observe an application  $h$  from  $n$  fields  $(\mathbf{X}_1, \dots, \mathbf{X}_n)$   
of the associated input process  $\mathbf{X}$  and  $n$  vectors  $(\mathbf{Y}_1, \dots, \mathbf{Y}_n)$

$$h : \left| \begin{array}{ccc} \mathcal{M}_N \times (\mathbb{R}^d)^N & \rightarrow & \mathbb{R}^p \\ \mathbf{X} & \mapsto & \mathbf{Y} \end{array} \right.$$

We propose the following steps to lead to sensitivity analysis.

- ▶ 1. Dimension reduction via Karhunen-Loeve for each input block
- ▶ 2. Approximate of the link between KL coefficients and vectorial outputs by chaos
- ▶ 3. Post-process functional chaos coefficients to derive Sobol' indices

# Variance-based sensitivity analysis for functional inputs

Methodology step 1/3: Dimension reduction by Karhunen-Loeve

We use the Karhunen-Loeve decomposition to find the  $(\lambda_k, \varphi_k)_{k \geq 1}$  solutions of the Fredholm equation:

$$\int_{\mathcal{D}} \mathbf{C}(\mathbf{s}, \mathbf{t}) \varphi_k(\mathbf{t}) d\mathbf{t} = \lambda_k \varphi_k(\mathbf{s}) \quad \forall \mathbf{s} \in \mathcal{D}$$

The SVD decomposition helps to approach the covariance function  $\mathbf{C}$  by its empirical estimator.

# Variance-based sensitivity analysis for functional inputs

## Methodology step 1/3: Dimension reduction by Karhunen-Loeve

The linear projection function  $\pi_{\lambda,\varphi}$  of the Karhunen-Loeve decomposition writes:

$$\pi_{\lambda,\varphi} : \left\{ \begin{array}{ll} L^2(\mathcal{D}, \mathbb{R}^d) & \rightarrow \mathcal{S}^{\mathbb{N}} \\ f & \mapsto \left( \frac{1}{\sqrt{\lambda_k}} \int_{\mathcal{D}} f(\mathbf{t}) \varphi_k(\mathbf{t}) d\mathbf{t} \right)_{k \geq 1} \end{array} \right.$$

This integral is replaced by a specific weighted and finite sum and to write the projections of the  $j$ -th marginal of  $i$ -th input field  $\mathbf{X}_i^j$  by multiplication with the projection matrix  $\mathbf{M}_j^i \in \mathbb{R}^{K_j} \times \mathbb{R}^{Nd}$ :

$$\mathbf{M}_j^i \mathbf{X}_i^j = \begin{pmatrix} \xi_1^j \\ \dots \\ \xi_{K_j}^j \end{pmatrix} \in \mathbb{R}^{K_j}, \forall i \in [1, n], \forall j \in [1, d]$$

with  $K_j$  the retained number of modes in the decomposition of the  $j$ -th input

# Variance-based sensitivity analysis for functional inputs

Methodology step 1/3: Dimension reduction by Karhunen-Loeve

The projections of all the  $d$  components of  $n$  fields are assembled in the  $Q$  matrix:

$$\mathbf{Q} = \mathbf{M}\mathbf{X} = \begin{pmatrix} \mathbf{M}_1\mathbf{X}^1 \\ \dots \\ \mathbf{M}_d\mathbf{X}^d \end{pmatrix} \in \mathbb{R}^{K_T} \times \mathbb{R}^n$$

with  $K_T = \sum_{j=1}^d K_j$  the total number of modes accross input components

# Variance-based sensitivity analysis for functional inputs

## Methodology step 2/3: Link KL coefficients to outputs

Then a functional chaos decomposition is built between the projected modes sample  $\mathbf{Q}$  and the output samples  $\mathbf{Y}$

$$\tilde{g}(x) = \sum_{k=1}^{K_c} \beta_{\alpha_k} \Psi_{\alpha_k}(x)$$

The final metamodel consists in the composition of the Karhunen-Loeve projections and the functional chaos metamodel.

$$\tilde{h} : \left| \begin{array}{ccccc} \mathcal{M}_N \times (\mathbb{R}^d)^N & \rightarrow & \mathbb{R}^{K_T} & \rightarrow & \mathbb{R}^p \\ \mathbf{X} & \mapsto & \mathbf{Q} & \mapsto & \mathbf{Y} \end{array} \right.$$

A limitation of this approach is that the projected modes sample has a dimension  $K_T$  so the dimension of the input fields  $\mathbf{X}_i$  and the associated number of modes must remain modest.

# Variance-based sensitivity analysis for functional inputs

Methodology step 2/3: Link KL coefficients to outputs

From the chaos decomposition:

$$\tilde{g}(x) = \sum_{k=1}^{K_c} \beta_{\alpha_k} \psi_{\alpha_k}(x)$$

Lets expand the multi indices notation:

$$\psi_{\alpha}(x) = \prod_{j=1}^{K_T} P_{\alpha_j}^j(x_j)$$

with  $\alpha$  that contains the marginal degrees associated to the  $K_T$  input components

$$\alpha \in \mathbb{N}^{K_T} = \underbrace{\{\alpha_1, \dots, \alpha_{K_1}\}}_{K_1}, \dots, \underbrace{\{\alpha_{K_T-K_d}, \dots, \alpha_{K_T}\}}_{K_d}$$

## Variance-based sensitivity analysis for functional inputs

Methodology step 3/3: Derive Sobol' indices from chaos coefficients

Sobol indices of the input field component  $j \in [1, d]$  can be computed from the coefficients of the chaos decomposition that involve the matching KL coefficients.

For the first order Sobol indices we sum over the multi-indices  $\alpha_k$  that are non-zero on the  $K_j$  indices corresponding to the KL decomposition of  $j$ -th input and zero on the other  $K_T - K_j$  indices (noted  $G_j$ ):

$$S_j = \frac{\sum_{k=1, \alpha_k \in G_j}^{K_c} \beta_{\alpha_k}^2}{\sum_{k=1}^{K_c} \beta_{\alpha_k}^2}$$

For the total order Sobol indices we sum over the multi-indices  $\alpha_k$  that are non-zero on the  $K_j$  indices corresponding to the KL decomposition of the  $j$ -th input (noted  $GT_j$ ):

$$S_{T_j} = \frac{\sum_{k=1, \alpha_k \in GT_j}^{K_c} \beta_{\alpha_k}^2}{\sum_{k=1}^{K_c} \beta_{\alpha_k}^2}$$

This generalizes to higher order indices.

# Variance-based sensitivity analysis for functional inputs

## Outlook

- ▶ Development is settling down
- ▶ Expected to land in OT 1.20 (fall 2022)
- ▶ Extension to Vector  $\mapsto$  Field, Field  $\mapsto$  Field ?
