Seismic input characterization

28 SEISMIC SIGNALS

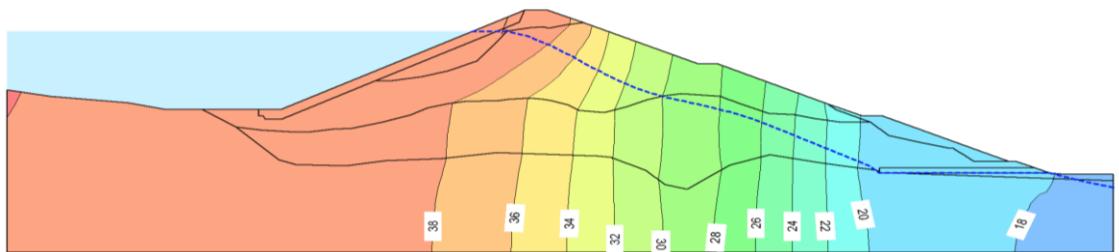

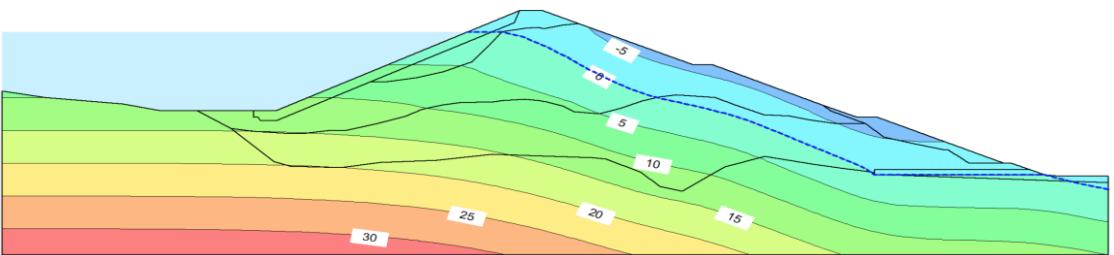

- 7 SLO (Operability Limit State),
- 7 SLD (Damage Limit State);
- 7 SLV (Life's Safeguard Limit State);
- 7 SLC (Collapse Limit State).

A constant zero value tale of 5 seconds is added at the end of each signal to observe the free oscillations state.

Signal are applied at the dovetail's level (hp. of close bedrock) and are filtered by the upper layers, generating an amplification compared to the "free field" signal.

Initial distribution of interstitial pressures

Interstitial pressures effect is more influent in drained conditions, where the resistance is also governed by effective pressure.

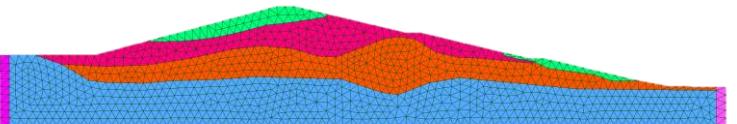

Hydrodynamic characterization

The **THM** (Thermo-Hydraulique-Mecanique) modellation allows the definition and the evolution's study of porous materials (saturated and unsaturated). The hydrodynamic load is negligible compared to the seismic one.

```

Geotechnical data

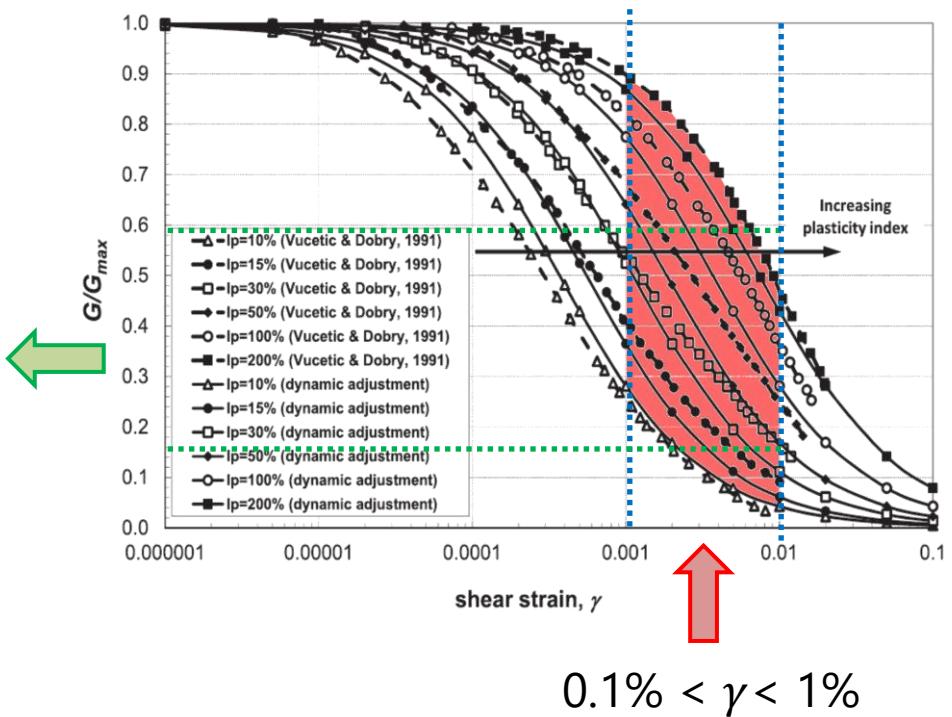

The available geotechnical data are insufficient to define Hujeux parameters (and also Cam-Clay one). Mohr-Coulomb's law is adopted as its definition requires only few parameters.

- Sliding surfaces identification (maximum shear strain);
- Assumption of deformation cycles between 0.1 and 1% contained into those surfaces.

Shear modulus reduction between 20÷50 % of the original one ($c_{Ered}=0.2\div 0.5$).

From P. J. Vardanega, and M. D. Bolton, *Stiffness of Clays and Silts: Normalizing Shear Modulus and Shear Strain*, JOURNAL OF GEOTECHNICAL AND GEOENVIRONMENTAL ENGINEERING, ASCE / SEPTEMBER 2013

Parameters decay

Assumed according to the cyclical behaviour of the material. A decay factor is hypothesized for the reduction of elastic properties (c_{Ered} is applied to shear modulus).

```

Parametric analysis

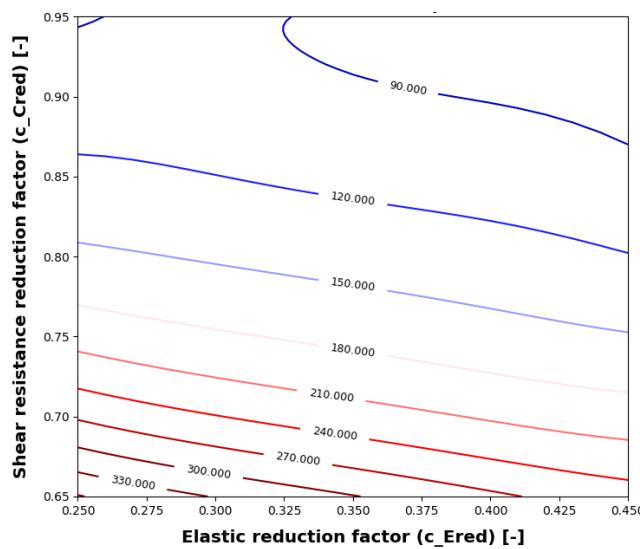

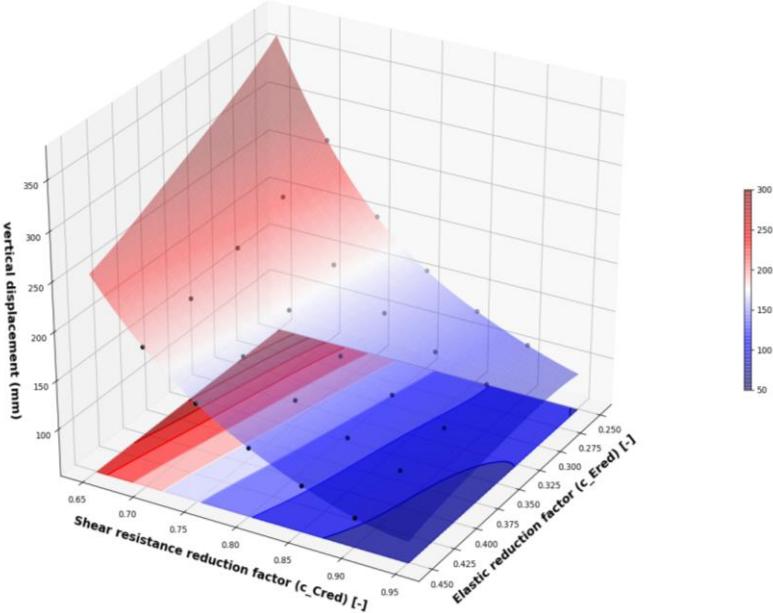

Creation of a grid of reduction factors values used as inputs for **25 analysis**. The output is set as the maximum vertical displacement of the freeboard.

SLC_M3 metamodel

SLC_M7 metamodel

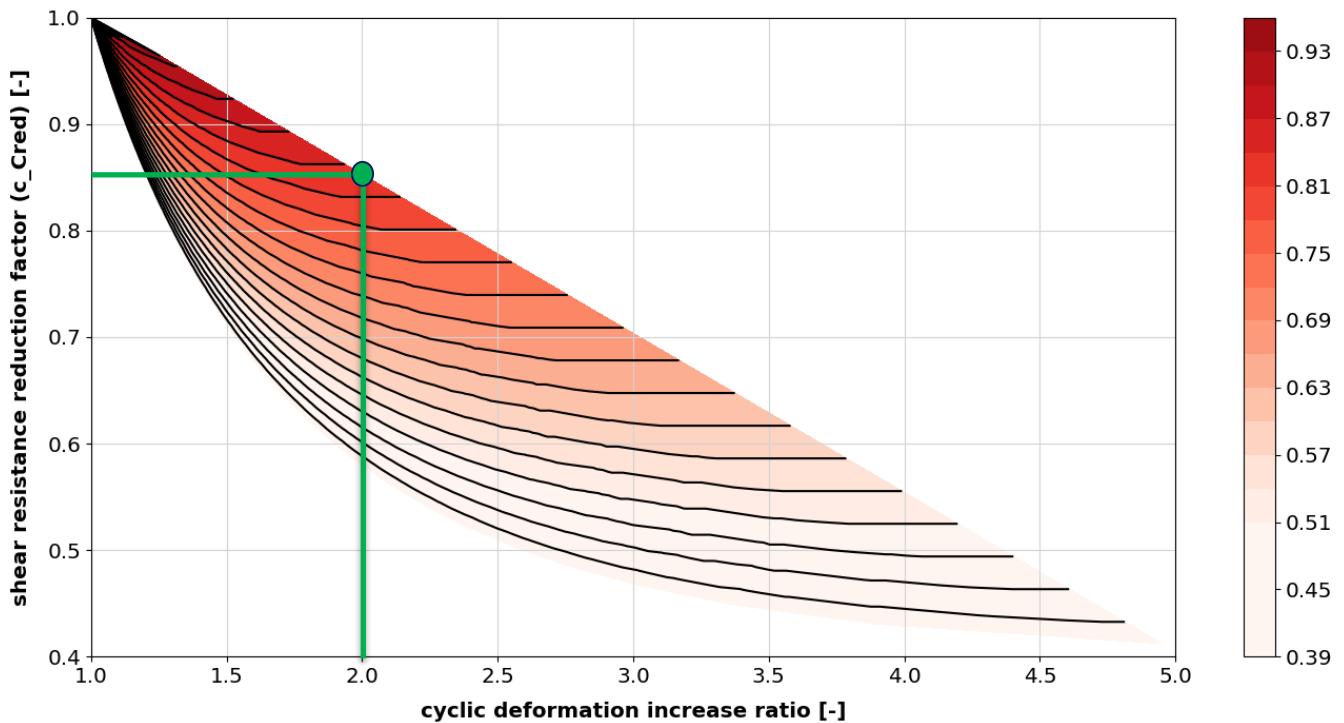

Metamodel

A **metamodel** (Kriging) has been set up based on different time history. The **input-output relation** is described by an interpolating surface. It allows to explore the design space, make predictions on untried values and assess the influence of each parameters on the output.

Analytical estimation

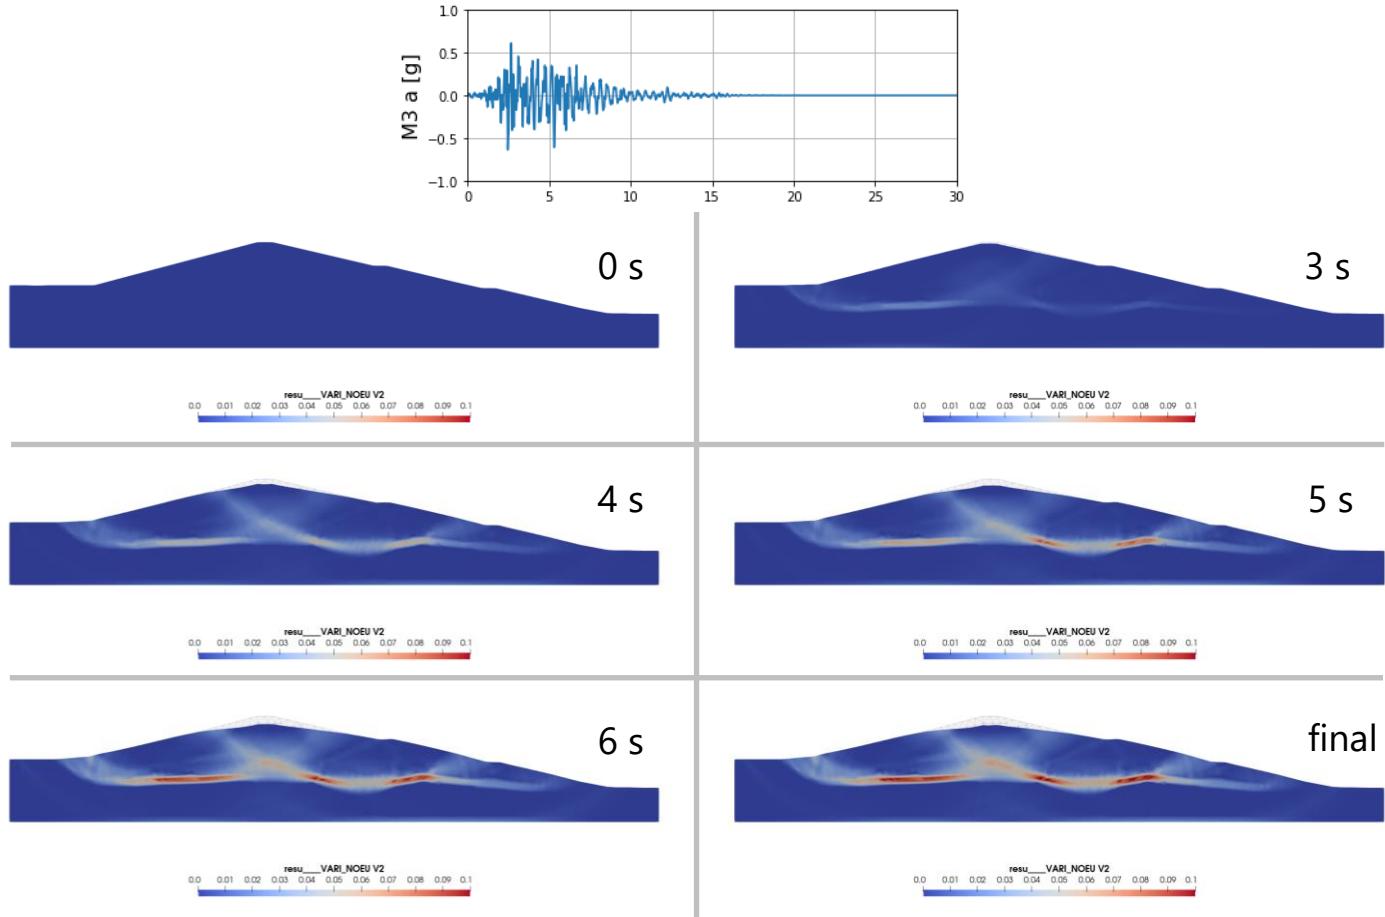

A metamodel (Kriging) has been set up based on 25 analysis (SLC_M7) where at each set of input variables (c_{Ered} , c_{Cred}) is associated an output (freeboard vertical displacement). It allows to explore the relationship between inputs and outputs and make predictions on untried values.

OpenTURNS and code_aster, combined or standalone, offer an extremely useful set of tools the following purposes:

- The **model calibration**, an important phase of the structural health monitoring is feasible combining different techniques;
- Validated surrogate or **meta-models** have a great efficiency and can be adopted for different purposes;
- The **damage identification** procedure can be applied both in qualitative and quantitative approaches;
- The **uncertainty quantification** can be approached to better understand the input and/or output parameters correlation;
 - These techniques become application-prone in the engineering context as **decision tools**.
